Conclusions

Coxsackievirus A21: Mode of action

Coxsackievirus A21 (CAVATAK™, CVA21) is a naturally occurring enterovirus of the family Picornaviridae. It is a replication-competent virus that induces mild upper respiratory symptoms during natural infection of humans. CVA21 also displays potent oncolytic activity against both in vitro cultures of human cancer cells and against in vivo xenografts of human cancers in mouse models of melanoma, prostate cancer, breast cancer and multiple myeloma, all of which exhibit high surface ICAM-1 expression. In a mouse melanoma xenograft model, CVA21 challenge studies demonstrated that progeny virus released from infected cells is capable of targeting adjacent cells, entering the systemic circulation, and destroying micro-metastatic foci.

Introduction

Coxsackievirus A21 (CVA21) is a naturally occurring replication-competent virus; it binds to the N-terminal domain of the intercellular adhesion molecule-1 (ICAM-1); and targets cancer cells expressing high surface levels of ICAM-1. Numerous different types of cancer cells express high levels of ICAM-1.

Objectives

Primary Objective
- To determine the safety of two equal doses of CVA21 given by intratumoral injection 48 hours apart, with total doses of 2 x 10^7 TCID50, 2 x 10^8 TCID50, and 2 x 10^9 TCID50.

Secondary Objectives:
- To evaluate clinical responses (reflecting potential CVA21 activity) of the injected nodules as measured by calipers and ultrasound.
- To determine clinical responses in non-injected tumours, as measured by CT scan.
- To establish predictors and correlates of adverse events.

Methods: Dosing schedule

A single cutaneous melanoma deposit of 9 stage IV melanoma patients (3 cohort of 3 patients) was injected with 2 doses of CVA21 (1.0 x 10^7 TCID50 or 1.0 x 10^8 TCID50, Viralytics Limited) 48 hours apart. The viral inoculum was diluted to 10% of the target lesion in saline up to a maximum of 10mL. The average longest diameter of the injected lesions was 3.2 ± 0.9 cm.

Results

Figure 1. Timecourse of the development of patient serum anti-Coxsackievirus A21 neutralising antibody.

Figure 2. Serum levels of Coxackievirus viral RNA as monitored by qRT-PCR.

Figure 3. Changes in injected lesion volumes as assessed by ultrasound measurement.

Discussion

- Nine patients tolerated two intratumoral injections of CVA21 up to a final accumulated dose of 2 x 10^9 TCID50 such as a MTD of CVA21 in excess of 10^9 TCID50 was not reached.
- Following CVA21 injections, 5 of 9 (55.6%) patients experienced transient reductions in injected tumor volume or tumor stabilization.
- No objective responses were observed, however, 2 patients displayed stable disease as assessed by RECIST 1.0 following CT evaluation.
- CVA21 viral RNA was detected by qPCR in 3 of 5 injected lesions on trial termination, even in the presence of high level serum anti-CVA21 neutralising antibody.
- Elevated levels of serum GM-CSF were observed from 2 patients displaying notable reductions in the volume of injected lesions, suggesting a possible immune-mediated anti-tumor response.
- No evidence of post-injection CVA21 excretion in urine, feces and sputum was observed.

Conclusions

Potential anti-tumor activity and patient tolerability of intralesionally delivered CVA21, provides a solid foundation for Phase II investigations employing a multi-dose administration schedule to study the efficacy and safety of CVA21 in patients with late stage melanoma and other advanced solid cancers.

Phase II: CALM Study design
